NAVIGATOR study

Abstract

Objective To examine the degree to which use of β blockers, statins, and diuretics in patients with impaired glucose tolerance and other cardiovascular risk factors is associated with new onset diabetes.

Design Reanalysis of data from the Nateglinide and Valsartan in Impaired Glucose Tolerance Outcomes Research (NAVIGATOR) trial.

Setting NAVIGATOR trial.

Participants Patients who at baseline (enrolment) were treatment naïve to β blockers (n=5640), diuretics (n=6346), statins (n=6146), and calcium channel blockers (n=6294). Use of calcium channel blocker was used as a metabolically neutral control.

Main outcome measures Development of new onset diabetes diagnosed by standard plasma glucose level in all participants and confirmed with glucose tolerance testing within 12 weeks after the increased glucose value was recorded. The relation between each treatment and new onset diabetes was evaluated using marginal structural models for causal inference, to account for time dependent confounding in treatment assignment.

Results During the median five years of follow-up, β blockers were started in 915 (16.2%) patients, diuretics in 1316 (20.7%), statins in 1353 (22.0%), and calcium channel blockers in 1171 (18.6%). After adjusting for baseline characteristics and time varying confounders, diuretics and statins were both associated with an increased risk of new onset diabetes (hazard ratio 1.23, 95% confidence interval 1.06 to 1.44, and 1.32, 1.14 to 1.48, respectively), whereas β blockers and calcium channel blockers were not associated with new onset diabetes (1.10, 0.92 to 1.31, and 0.95, 0.79 to 1.13, respectively).

Conclusions Among people with impaired glucose tolerance and other cardiovascular risk factors and with serial glucose measurements, diuretics and statins were associated with an increased risk of new onset diabetes, whereas the effect of β blockers was non-significant.

Trial registration ClinicalTrials.gov NCT00097786.

Over the 14 year stu with no history of diabete Of these, 227 994 (4 prevention, while 24 secondary preventic was 73 (interquartile women.

There was no significantly increased risk an fluvastatin (0.95, 0.81 to 1.11) or lovastatin (absolute risk for incident diabetes was about person years for atorvastatin and rosuvastat a slightly lower absolute risk with simvastatin person years) compared with pravastatin (23 years). Our findings were consistent regardle used for primary or secondary prevention of Although similar results were observed when potency, the risk of incident diabetes associa became non-significant (adjusted hazard rat dose was taken into account.

Abstract

Objective To examine the risk of new onset diabetes among patients treated with different HMG-CoA reductase inhibitors (statins).

Design Population based cohort study with time to event analyses to estimate the relation between use of particular statins and incident diabetes. Hazard ratios were calculated to determine the effect of dose and type of statin on the risk of incident diabetes.

Setting Ontario, Canada.

Participants All patients aged 66 or older without diabetes who started treatment with statins from 1 August 1997 to 31 March 2010. The analysis was restricted to new users who had not been prescribed a statin in at least the preceding year. Patients with established diabetes before the start of treatment were excluded.

Interventions Treatment with statins.

Main outcome measure Incident diabetes.

Results Compared with pravastatin (the reference drug in all analyses), there was an increased risk of incident diabetes with atorvastatin (adjusted hazard ratio 1.22, 95% confidence interval 1.15 to 1.29), rosuvastatin (1.18, 1.10 to 1.26), and simvastatin (1.10, 1.04 to 1.17). There was no significantly increased risk among people who received fluvastatin (0.95, 0.81 to 1.11) or lovastatin (0.99, 0.86 to 1.14). The absolute risk for incident diabetes was about 31 and 34 events per 1000 person years for atorvastatin and rosuvastatin, respectively. There was a slightly lower absolute risk with simvastatin (26 outcomes per 1000 person years) compared with pravastatin (23 outcomes per 1000 person years). Our findings were consistent regardless of whether statins were used for primary or secondary prevention of cardiovascular disease. Although similar results were observed when statins were grouped by potency, the risk of incident diabetes associated with use of rosuvastatin became non-significant (adjusted hazard ratio 1.01, 0.94 to 1.09) when dose was taken into account.

Do Statins Alter Glucose/Insulin Metabolism?

- 1. Genetic association
- 2. Affect insulin secretion through direct, indirect or combined effects on calcium channels in pancreatic Beta-cells
- 3. Reduced translocation of glucose transporter 4
- 4. Decreases other important downstream products, such as coenzyme Q10, farnesyl pyrophosphate, geranylgeranyl pyrophosphate and dolichol
- Interference with intracellular insulin signal transduction pathways via inhibition of necessary phosphorylation events and reduction of small GTPase action, inhibition of adipocyte differentiation leading to decreased PPAR gamma
- 6. Decrease Adiponetin, adiopocytokine

Guidelines

 Individuals receiving statin therapy should be evaluated for new-onset diabetes mellitus according to the current diabetes screening guidelines (93). Those <u>who develop diabetes</u> <u>mellitus during statin therapy should be</u> 	B (Moderate)	44	Iţ	В
encouraged to adhere to a <u>heart healthy dietary</u> pattern, engage in <u>physical activity</u> , achieve and				
maintain a healthy body weight, cease tobacco				
use, and continue statin therapy to reduce their				
risk of ASCVD events.				

Guidelines

• The absolute reduction in the risk of CVD in high risk patients outweighs the possible adverse effects of a small increase in the indicence of diabetes.

ESC/EAS guidelines for the management of dyslipidaemias Atherosclerosis 2011;217:3-46

in Pts c/s RFs* for DM

Lancet 2012:380:581

in Pts c/s RFs* for DM

*MetS, IGT (101-125 mg/dL), BMI>30 kg/m2, or HbA1c> 6%

Statins increase the risk of dysglycemia and or DM in a dose dependent fasion

- Absolute terms at low dose prevent 5-7 CVD events for every 1 new case of DM over 1000 person years of treatment
- Fro intensive statin therapy this is 3 CVD cases prevented per 1 extra case of DM

Statin, Risk of DM, and Outcomes in the General Population (Taiwan National Health Insurance)

Low CV risk subjects

High CV risk subjects

Statin, Risk of DM, and Outcomes in the General Population (Taiwan National Health Insurance)

Primary CV prevention 2ndary CV prevention

Summary & Conclusions (I)

- Diabetes is a major risk factor for macrovascular including CVD and microvascular disease.
- Statin increases the *incidence of new onset* <u>diabetes.</u>
- The <u>beneficial effects of statins</u> including high dose statins <u>outweigh the risk of statin for</u> <u>new onset diabetes</u>, therefore, statin should <u>be continued in high CV risk patients</u>.

Summary & Conclusions (II)

- <u>Differential effects</u> on insulin sensitivity and incidence of new onset diabetes <u>among statins</u> have been noted.
- Dose reduction and careful selection of statin should be considered by the risk benefit assessment for reduction of CVD and risk of DM in patients with high risk for developing diabetes, especially in East-Asian population and low cardiovascular risk.
- Further researches for this topic are warranted in the future.

Thank you for your attention!!!

Intracellular Actions of Statins

Fig. 2 – Intracellular actions of statins. Lipophilic statins penetrate the cell membrane easier those which are hydrophilic, and therefore are likely to have more extrahepatic effects. Statins have been shown to reduce membrane IR phosphorylation or expression, resulting in insulin resistance. Within the cell, insulin signalling and GLUT4 transport can be altered by changes in IRS-1, Akt, Rab4, Ras, IR-β, or membrane fraction of RhoA, all of which have been shown to be inhibited by statin therapy. Individual statins have been shown to affect different factors, as illustrated in this figure. A, atorvastatin; C, cerivastatin; L, lovastatin; Cav1, caveolin-1; FPP, farnesyl pyrophosphate; GGPP, geranylgeranyl pyrophosphate; GLUT4, glucose transporter; GTP, guanosine triphosphate; IGF, insulin like growth factor; IR, insulin receptor; IRS-1, Insulin receptor substrate; PI3K, phosphatidylinositol 3-kinase; S, simvastatin.

Mevalonate Pathway and Statin Mechanisms

Fig. 1 – Mevalonate pathway and statin mechanisms.Mevalonate pathway inhibition by statins causes reductions in other downstream products. The major components which may be involved in new-onset diabetes are GGPP, FPP, dolichol and coenzyme Q10. Decreases in isoprenoids FPP and GGPP result in decreased GLUT4 glucose uptake and decreased Ras activity. Reduced dolichol results in reduced IR membrane levels. CoQ10 is necessary to produce mitochondrial ATP to stimulate insulin secretion via calcium influx in β-cells.ADP, adenosine diphosphate; ATP, adenosine triphosphate; Ca²⁺, Calcium ions; CoQ10, coenzyme Q10; FPP, famesyl pyrophosphate; GGPP, geranylgeranyl pyrophosphate; GLUT4, glucose transporter 4; IR, insulin receptor; K⁺, potassium ions.
